ABSTRACT

Aims Anxiety among medical students is a major psychological problem and in the newest meta-analysis, its global prevalence rate is estimated to be 33.8%. Accordingly and since spiritual intelligence training can affect to resolve fundamental issues and enhance individuals' adaptability, therefore the aim of this study was to determine the effect of spiritual intelligence training on the anxiety of medical sciences students.

Materials & Methods In this randomized clinical trial in 2016, 50 students from Yasuj and Larestan Universities of medical sciences-Iran were selected using purposive sampling method and divided into intervention and control groups with the equal members through random block allocation of 4. While the control group did not receive any intervention, the spiritual intelligence training accomplished for the intervention group. At the beginning of the study and one month after intervention, the trait and state anxiety of students were measured using Spielberger state-trait anxiety inventory. Data were analyzed using SPSS 21 software, through Chi-square test, independent t-test, and paired t-test.

Findings At the beginning of the study, there was no significant difference between the intervention and control groups regarding the amount of the trait and state anxiety ($p > 0.05$). One month after the intervention, the amount of the trait and state anxiety in the intervention group was significantly less than these amounts in the control group, as well compared to these amounts at the beginning of the study ($p < 0.05$).

Conclusion The spiritual intelligence training causes a decrease in the trait and state anxiety of medical sciences students.

Introduction

The term "anxiety" originates from the Latin word "anxieta" meaning mental harassment in some unknown events, and a Greek term "anxo" meaning stress and suffocation. Anxiety is a term used to describe the experiences of ordinary people when faced with threat, danger or stress, and is manifested by severe negative emotions and symptoms, like physical stress in as physical, cognitive, and behavioral changes [1-3].

The abnormal functioning of GABA neurotransmitters, serotonin, norepinephrine and dopamine, as well as the abnormal response of chemical receptors lead to anxiety, in which a person with anxiety predicts a danger or misery in future. This condition may indirectly as trait anxiety or directly as state anxiety affects people's lives and causes psychological and social changes, such as doubts, inability to make decisions, sensitivity, anger, loneliness, helplessness, and hatred [1, 4].

Trait anxiety is associated with the potential for anxiety, through which individuals are prepared to perceive anxious situations, such as experiencing danger or threatening situations, and in response to such situations, severely reveal anxious reactions; whereas state anxiety refers to the tangible and visible response to anxiety at certain times and severely inappropriate situations, such as at discussions, loss of social status or threatened human security and health [5].

Students, as the most important human capital, are the most influential factors to form the nature of each society and the cultural, social and economic development that their mental health, including self-acceptance, positive relationship with others, independence, environmentally dominant, purposefulness in life, and personal growth, in addition to positive personal effects, play an important role in the dynamics and efficiency of societies [6-8].

Despite the importance of students' mental health, previous studies have suggested that entering university as an environment different from school environment and facing new situations poses problems, such as stress and anxiety for students and jeopardizes their mental health [9-11].

Evolution-based crises associated with adolescence, being far from the family, fear of self-expression while facing with others, a desire for show-off, being exposed with the opposite sex, living with other students in the dormitory, lack of facilities, financial problems, unfamiliar environments, dissatisfaction with the major, academic problems, competition with other students, tests and several classes to attend, and being worried about job prospects are factors that increase trait anxiety and state anxiety in students [12-16].

Anxiety has always been seen among medical students due to the overwhelming nature of these

disciplines and the necessity of practices based on theoretical education in the patient's bedside and in the latest meta-analysis, the prevalence of this psychological disorder in medical students is estimated 33.8% worldwide. Accordingly, appropriate interventions at three levels of prevention are important to control medical students' anxiety [11, 17-20].

Drug therapy as a routine intervention can be effective in improving anxiety and its symptoms by balancing biochemical neurochemical mediators. However, since other psychological pathological processes, such as decreased levels of psychological immunity, unconscious effects, pathophysiological changes originating from the environment, the individuals' attitudes toward events and their supportive system have also been effective in causing anxiety and their interventions have less complications than drug interventions, therefore, nowadays non-pharmacological therapies have been considered in anxiety-related interventions [3, 21].

One of the non-pharmacological interventions regarding anxiety is spiritual intelligence training. Spiritual intelligence is a profound intuition that makes a person with more self-conscious about the dimensions of himself, inner knowledge based on good understanding and unity with the universe and all living on it and also the ability to use sacred elements, finding meaning in life, high vigilance and transcendence, use an adaptive approach that leads to the production of valuable results. Accordingly, spiritual intelligence training provides the means for a person to use spiritual information in a consistent manner to solve life's problems and finding meaning in life and values to achieve his goals [22, 23].

Considering the above issues and regarding the fact that spiritual intelligence training by facilitating the communication with a superior sacred power, developing beliefs, norms, and values related to this superior power and cultivating spiritual capacities and abilities can make life meaningful and valuable and help the individual solve basic problems and increase adaptability [24-27], this study aimed at determining the effect of spiritual intelligence training on anxiety of medical students.

Materials and Methods

This study is a randomized clinical trial that was conducted in the Yasuj and Larestan Universities of Medical Sciences, Iran in 2016. The purposive sampling method was done and 424 students of the Yasuj and Larestan Universities were selected. After explaining the research objectives for the students, the consent form and the research tools were distributed among them. Of these students, 385 cases were willing to participate in the study and completed the written informed consent form. Of those willing to participate in the research, a student who was eligible regarding the inclusion and

exclusion criteria was allocated to the intervention and control groups through random allocation with a block size of four and continued until the sample size in each group reach 25 subjects (a total of 50 subjects).

Inclusion criteria included obtaining the score of 43 and above (cut-off point) in trait and state anxiety in the Spielberger State-Trait Anxiety Inventory and the exclusion criteria were a diagnosed mental illness or chronic physical illness.

The demographic and background information questionnaire was used to collect characteristics, such as age, sex, marital status, field of study, university entry year, university name, place of residence, history of diagnosed chronic physical and mental diseases and also the Spielberger State-Trait Anxiety Inventory was used as research tools.

Spielberger State-Trait Anxiety Inventory: The 40-item State-Trait Anxiety Inventory was developed in 1971 by Spielberger. It takes about 6 minutes to complete this self-administrated checklist. This inventory consists of two parts of 20 questions for measuring hidden anxiety (trait anxiety) and 20 questions for measuring apparent anxiety (state anxiety) with different instructions for completing each section, therefore, the examiner emphasized to the subjects that they should study both instructions carefully and choose the most appropriate option.

According to the test protocol, the subjects in 20 questions regarding trait anxiety based on their usual and frequent feelings should choose an option from "almost never", "sometimes", "most often" and "almost always" that are scored 1 to 4. It is worth noting that the questions 21, 23, 26, 27, 30, 33, 34, 36 and 39 are reversely scored and the answers are scored 4 to 1, respectively.

Also, according to its protocol, the subjects should answer 20 questions regarding state anxiety based on their own emotions at the time of completing the form. They should choose an option that best expresses their intensity of feeling on a four-choice scale "very low", "low", "many" and "too many". The answers are scored 1 to 4. It is worth noting that the questions 1, 2, 5, 8, 10, 11, 15, 16, 19 and 20 are reversely scored and the answers are scored 4 to 1, respectively.

To obtain the score of each type of anxiety, the total score of the questions is calculated, and higher scores indicate more anxiety in the respondent. The range of trait and state anxiety varied between 20 and 80, with a score of 43 being suggested as the cut-off point. Also, according to the scores obtained for each type of anxiety, the trait anxiety (hidden anxiety) and situational anxiety (apparent anxiety) can be classified (Table 1).

The validity of the Spielberger Inventory was assessed through construct validity and approved and obtained 0.75- 0.83 due to its correlation coefficient compared with other validated anxiety

assessment questionnaires, such as the Anxiety Scale Questionnaire (ASQ) and the Taylor's Manifest Anxiety Scale (TMAS). Its validity has also been evaluated and validated in a concurrent validity. The reliability of the Spielberger State-Trait Anxiety Inventory was confirmed in the range of 0.87-0.91 based on the Cronbach's alpha coefficient reported in previous studies [28, 29]. In the present study, Cronbach's alpha coefficient of Spielberger inventory was 0.93.

The control group did not receive any intervention, whereas the intervention group was subjected to eight 90-minute sessions of spiritual intelligence training, once every 4 days. In training sessions, topics on defining and explaining spiritual intelligence and its components, self-awareness, intelligent awareness, transcendental consciousness, personal meaning, meaning in life, truth, and honesty were presented using lectures, questions, answers, and some practices based on the protocol (Table 2).

Table 1) Classification of the anxiety severity based on the Spielberger State-Trait Anxiety Inventory

Classification of the anxiety severity	State anxiety score	Trait anxiety scores
Mild anxiety	20-31	20-31
Moderate to low anxiety	32-42	32-42
Moderate to high anxiety	43-53	43-52
Relatively severe anxiety	54-64	53-62
Sever anxiety	65-75	63-72
Very severe anxiety	76-80	73-80

Table 2) The content of the spiritual intelligence training sessions

First session
Introduction, expressing expectations and rules, defining and explaining spiritual intelligence and its components, defining consciousness and self-awareness, and entering spiritual states while being conscious, training awareness of your own anxiety response
Second session
Explaining the effects of spiritual intelligence on daily life and interactions, training existential concepts (reality, death), training mental imagery, recognizing your strengths and weaknesses
Third session
Describing phobias-related thoughts and behaviors, supporting patients in coping with long-avoided anxieties, critical thinking training
Fourth session
Personal meaningfulness, training different coping styles, ability and training making a purposeful life and the material and physical experiences, ability to adorn daily activities with a sense of spirituality and holiness
Fifth session
Meaning of life, experiencing meaning and communicating between life's valuable activities and experiences, revisiting your world with an emphasis on the meaning of life
Sixth session
Familiarity with the visualization and vision concepts, transcendent consciousness and mindfulness training, holism and understanding and identification of the dimensions and capabilities of yourself, others, and the world
Seventh session
Familiarity with the concepts, including truth, honesty, self-acceptance, accepting others, virtuous behaviors, such as forgiveness, remission, gratitude, positive thinking and optimism, anger control skills training, daring, positive interpersonal relationships, and stress control skills
Eighth session
Familiarity with the holiness, purity and superiority, alliance, unity and integrity, spiritual education, development of spiritual awareness

One month after the end of the intervention, the Spielberger inventory was again completed by all subjects and the collected data were analyzed by SPSS 21 at 95% confidence level. Inter-group comparison of the demographic quantitative variables, including age and the dependent variables, including trait and state anxiety with normal distribution was performed using independent t-test. Chi-square test was used to compare the qualitative variables, including demographic and background variables, such as gender, marital status, field of study, year of entry to university, university name, and place of residence. Paired t-test was used for intra-group comparison of the dependent variables, including trait and state anxiety with normal distribution.

All ethical considerations, such as obtaining the written informed consent from the students, making the subjects informed about the possibility to withdraw from the study, confidentiality of the information and general use of data based on the study objectives were observed. Also, considering the positive effects of spiritual intelligence training on trait and state anxiety of the intervention group, after preparing the final report of the research plan, spiritual intelligence training was conducted for the control group according to the protocol.

Findings

The mean age of the students was 22.04 ± 2.56 years. The mean age of the intervention and control groups were 22.56 ± 3.32 and 21.52 ± 1.36 years, respectively. There was no significant difference in age at baseline between the study groups ($p > 0.05$).

The intervention and control groups were homogenized at baseline in terms of demographic and background variables, such as gender, marital status, field of study, the year attending to the university, the university and place of residence and there was no significant difference between them ($p > 0.05$; Table 3).

The level of trait and state anxiety was similar in the medical students in the intervention and control groups at the baseline ($p > 0.05$). One month after intervention, trait and state anxiety were significantly lower in the intervention group compared to the control group ($p < 0.05$).

In the intra-group comparison, considering the difference between the mean scores of trait anxiety and state anxiety in the intervention group (-0.98 ± 7.96 and -12.76 ± 9.01 , respectively) and the control group (-1.80 ± 8.59 and -1.72 ± 9.33 , respectively), the trait anxiety and state anxiety of the intervention group decreased significantly after the intervention ($p < 0.05$); however, there was no significant difference in the control group after the intervention compared to the baseline ($p > 0.05$; Table 4).

Table 3) Comparison of the absolute and relative frequency distribution of demographic and background qualitative variables of medical students in intervention and control groups at baseline (n=25 per group; the numbers in parentheses are percent)

Variables	Intervention group	Control group	P. value
Gender			
Male	12 (48.0)	7 (28.0)	0.15
Female	13 (52.0)	18 (72.0)	
Marital status			
Single	23 (92.0)	24 (96.0)	0.55
Married	2 (8.0)	1 (4.0)	
Major			
Medicine/ Dentistry	2 (8.0)	5 (20.0)	0.32
Nursing/ Midwifery/ Medical emergencies	18 (72.0)	12 (48.0)

University			
Yasuj University of Medical Sciences	11 (44.0)	12 (48.0)	0.78
Lorestan School of Medical Sciences	14 (56.0)	13 (52.0)	
Living status			
Dormitory	21 (84.0)	22 (88.0)	0.68
At home	4 (16.0)	3 (12.0)	

Table 4) Comparison of the mean scores of trait and state anxiety of the medical students at baseline and one month after intervention in the two groups

Variables	Control group	Intervention group	Inter-group P. value
Trait anxiety			
At baseline	51.08±6.82	52.0±8.27	0.67
One month after intervention	49.28±7.47	42.2±9.42	0.005
Intra-group P value	0.31	0.0001	-
State anxiety			
At baseline	53.60±8.46	54.68±9.71	0.68
One month after intervention	51.88±6.78	41.92±8.41	0.0001
Intra-group P value	0.37	0.0001	-

Discussion

The findings of the present study indicated that the intervention and control groups were homogenized in terms of quantitative and qualitative demographic and contextual variables as well as trait and state anxiety at the baseline. Therefore, the changes in the dependent variables, including trait and state anxiety of the medical students after the intervention were due to the effect of spiritual intelligence training as an independent variable.

The results of inter-group comparison showed that one month after intervention, trait and state anxiety were significantly lower in the intervention group compared to the control group. Also, based on the results of intra-group comparison, the level of trait and state anxiety of the intervention group students decreased significantly one month after the intervention compared to the baseline, whereas in the control group, there was no significant

difference in trait and state anxiety of the students one month after the study intervention compared to the baseline; therefore, it can be concluded that spiritual intelligence training as a research intervention was able to differentiate between the intervention and control groups and significantly reduced trait and state anxiety in the medical students participating in the intervention group.

These results are consistent with results of Gutierrez [30], Souri *et al.* [31], and Ganjavi [32] studies. Also, the findings of the present study on the positive effects of spiritual intelligence training on reducing trait and state anxiety in medical students based on theoretical knowledge bases are also rational and justified; because spirituality is a stage, in which meaning, hope, comfort and inner peace are received, and spiritual intelligence represents a set of spiritual abilities and capacities that its application in daily life enhances one's adaptability. Belief in God or a superior power in the spirituality stage, by creating a sense of being supported, creates a sense of mastery over one's condition and positive attitude and reduces trait anxiety. Increasing the meaning, purpose and patience in life caused by increased spiritual intelligence also helps to cope with life's problems, thereby raising the threshold of tolerance and resilience to problems and stresses and reducing the state anxiety [33-35].

In addition to demonstrating the positive therapeutic effects of spiritual intelligence training in reducing trait and state anxiety in medical students in this study, due to the availability, cost-effectiveness, effect at shorter time, and minor side effects of this intervention, after confirming the results of this study in other relevant studies, spiritual intelligence training can be used as a complementary therapy to manage and control trait and state anxiety in medical students.

The present study also had some limitations; for example, the possible conversation between the students in the intervention and control groups and the possibility of exchanging information between them regarding educational contents and training could affect the results of the study. The possible reactions of individuals after learning about their anxiety at the baseline and also the involuntary and unconscious tendency to present their anxiety in a favorable range within a month after the end of interventions are other limitations of this study that could affect the results. Although students in the study were initially asked to refrain from attending other educational or psychological intervention courses or obtaining information during their study, however, the lack of attention to this issue by the intervention and control groups could affect the results of the study. Therefore, it is necessary to consider the above limitations to interpret the results of this study.

Considering the mentioned issues and in order to

improve the mental health of medical students, it is suggested to take necessary measures at the beginning of their entrance to university through holding workshops on spiritual intelligence training. Also, as medical students experience other negative consequences, such as depression, stress, etc., it is recommended that further studies examine the impact of spiritual intelligence training on these variables in medical students.

Conclusion

Spiritual intelligence training reduces trait and state anxiety in medical students and as an adjunctive therapy is effective in reducing anxiety and promoting mental health of medical students.
